Clinical	Comments	Diagnostic Considerations
Manifestation		
Meningeal disease	Subacute lymphocytic meningitis	
	Chronic lymphocytic meningitis	
	Dural involvement including pachymeningitis	
	Dural mass mimicking a meningioma	
Cranial nerves	Any cranial nerve can be involved.	Optic nerve involvement is usually manifest as swelling, T2 hyperintensity, and contrast
	Unilateral or bilateral lower facial nerve palsy is the most common cranial_nerve presentation. e1	enhancement of the optic nerve, optic nerve sheath, or_chiasm. e2
	Relatively frequent cranial neuropathies are optic neuropathy and eighth (acoustic/vestibular)	
	nerve dysfunction, which can be unilateral or bilateral.	
	Optic nerve involvement typically presents as a subacute or chronic optic neuritis. e2	
	Vision loss can be rarely due to extrinsic compression of the optic nerve from granulomatous	
	inflammation.	
	Isolated hearing loss or vertigo due to selective vestibulocochlear nerve involvement can occur;	
	bilateral sensorineural hearing loss should prompt an evaluation for NS. <sup>e3</sup>	
Brain	Small subcortical or periventricular white matter lesions may be asymptomatic and represent	Leptomeningeal enhancement, especially along the skull base, is the most common area
	inflammatory changes or small ischemic lesions resulting from arteriolar or venous	involved.
	inflammation-associated thrombosis.	Dural thickening and enhancement can be localized or diffuse, and may be hypointense
	NS has a predilection for the hypophysis-hypothalamus, resulting in a range of disturbances	on T2-weighted sequences.
	including hypothyroidism, hypogonadism, and the syndrome of inappropriate antidiuretic	Intraparenchymal granulomas can be seen as subcortical white matter lesions mimicking
	hormone (SIADH).	multiple sclerosis or micro-ischemic lesions, or can involve the deep grey matter.
	Communicating and non-communicating hydrocephalus can develop.	Large solitary aggregations of granulomas can masquerade as neoplasms.
		Diffusion weighted imaging of parenchymal disease is not bright, except rarely when an
		infarct results from vascular involvement.

Stroke can be due to in situ thrombosi, cardiogenic emboli, compression of a large vessel
by a granulomatous mass, sinovenous thrombosis, and intracerebral hemorrhage.

## Most patients have subpial intramedullary lesions and meningeal involvement is present in up to Spinal cord involvement can be intramedullary and indistinguishable from other causes of **Spinal cord** half the patients. e4 transverse myelitis. Patients may have gradually worsening myelopathic symptoms developing over months. e5 • Lesions are typically longitudinally-extensive. <sup>e6</sup> Myelitis may span more than 3 vertebral segments (predilection cervicothorac); NS is a The characteristic location of increased T2 signal in sarcoidosis is in the dorsal cord, and diagnostic consideration of a longitudinally extensive myelitis, including neuromyelitis optica contrast enhancement is typically subpial, dorsal, and irregular or nodular in appearance. spectrum disorder. e6 A characteristic finding on axial views is the "trident" sign of contrast enhancement extending from the dorsal subpial surface circumferentially bilaterally with a central spoke extending into the midline of the cord. e7 Meningeal involvement, with both dural thickening and enhancement, suggests NS. The pattern of large fiber nerve involvement varies widely, but most commonly presents as Electromyography (EMG), and nerve conduction study (NCS) findings are nonspecific **Neuropathy** either an axonal distal sensorimotor polyneuropathy with stocking-glove sensory symptoms and often indistinguishable from primary immune-mediated neuromuscular disorders. manifesting as pain and paresthesias or an asymmetric polyradiculoneuropathy in which EMG and NCS usually demonstrate changes consistent with axon loss; primary proximal and distal nerve segments are equally affected in a non-length dependent distribution. demyelinating abnormalities are occasionally found. While imaging studies are not routinely part of the neuropathy evaluation, MRI may Other neuropathy manifestations include mononeuritis multiplex, pure sensory or pure motor demonstrate gadolinium enhancement or enlargement of the affected nerve roots or neuropathy, and isolated plexus, root or peripheral nerve involvement (e.g. focal plexus. mononeuropathy). Less frequent are demyelinating neuropathies, which include chronic CSF findings are nonspecific and may be normal, but elevated protein is most commonly inflammatory demyelinating polyneuropathy, a Guillain-Barre syndrome (GBS)-like presentation, seen followed by pleocytosis. and multifocal motor neuropathy with conduction block. Histological confirmation of the affected tissue or evidence of systemic disease is required for a definite or probable diagnosis of sarcoidosis neuropathy, respectively. Biopsy of both muscle and nerve tissue increases the diagnostic yield as granulomas between muscle fibers tend to be larger and more developed than those found within the epineurium or endoneurium. e8,10,11

sweating changes can occur. e14  Skin biopsy with evaluation of intra-epidermal nerve fiber density (IENFD) can confirm the presence of a SFN, with reduced sweat gland density and innervation supporting an autonomic neuropathy.  Analysis of sweat production on quantitative sudomotor axon reflex testing (QSART) and corneal nerve fiber density on corneal confocal microscopy can also be helpful in confirming the clinical impression.	Para-	Small fiber neuropathy	Small fiber neuropathy (SFN)
Patients usually present with prominent somatic nerve dysfunction (e.g., pain, numbness, dysesthesias, and allodynia) *12 that is migratory and intermittent but can become constant and slowly progressive. Distribution is often in a non-length dependent pattern. **13*  Dysautonomia manifesting as orthostatic hypotension, gastrointestinal disturbances sweating changes can occur. **14*  Skin biopsy with evaluation of intra-epidermal nerve fiber density (IENFD) can confirm the presence of a SFN, with reduced sweat gland density and innervation supporting an autonomic neuropathy.  Analysis of sweat production on quantitative sudomotor axon reflex testing (QSART) and corneal nerve fiber density on corneal confocal microscopy can also be helpful in confirming the clinical impression.  For patients with prominent symptoms of dysautonomia, tilt table testing, heart rate variability measurements, and thermoregulatory sweat testing can be considered.  When evaluating a patient for "brain fog" consider infection, disordered sleep, hypothalamic pitultary dysfunction, depression, etc.  When evaluating a patient for fatigue consider pulmonary or cardiac disorders, depression, hypothyroidism, testosterone deficiency, corticosteroid myopathy, sleep	neurosarcoidosis	o Sensory	o The diagnosis of sarcoidosis-associated SFN should only be made in patients in
Patigue      numbness, dysesthesias, and allodynia) ************************************		o Autonomic	whom the diagnosis of extra-neural sarcoidosis or NS is certain.

			disorders, painful neuropathy, etc.

eTable 3. Differential Diagnosis of Sarcoidosis and Neurosarcoidosis

Potential multi-system	Comments
disorders to consider based	
on clinical context	
Systemic and CNS Infections	
Lyme disease [neuroborreliosis]	Obtain Lyme serologic studies in blood and CSF* 26
e25	
Neurosyphilis e27	Obtain syphilis serologic studies in blood and CSF*
CNS Fungal Infection including	Appropriate histologic stains and culture.* If chronic
coccidiomycosis,	meningitis, CSF cryptococcal antigen should be performed.
histoplasmosis, cryptococcus,	Consider fungal serology (Histoplasmosis, Blastomycosis,
spirotrichosis, blastomycosis	and Coccidiomycosis) depending on epidemiology, from
	serum and CSF. CSF Sporotrichosis serology in selected
	cases should be considered.
Tuberculosis <sup>e28</sup>	PPD*, Quantiferon gold assay*; Appropriate histologic stains
	and culture including from the CSF
Bacterial meningitis, especially	Culture*, PCR, serologic testing
subacute and chronic	
phenotypes	
Whipple's disease e29	PCR assay on CSF; small bowel or brain biopsy
Atypical mycobacterium (very	Appropriate histologic stains and culture*
rare in the absence of prior	
neurosurgery or hardware)	
Progressive multifocal	CSF PCR assay for JC virus, brain biopsy if high suspicion
leukoencephalopathy	and CSF negative per guidelines. e30 Note that sarcoidosis,

	even in the absence of therapeutic immunosuppression, can
	be sufficient as an illness to predispose to PML. e31
HIV	HIV serology*. CDC recommendations for diagnosis. e32
Other CNS viral infections	CMV PCR (most commonly ventriculitis or radiculomyelitis in
	a severely immunosuppressed patient); CSF VZV PCR and
	VZV antibodies; other viral PCRs and serologies as
	appropriate based on clinical context and local epidemiology
Parasitic infection (in the	Toxoplasma antibodies in serum and CSF (a negative serum
appropriate neuroimaging, CSF	test result usually rules out the infection) and biopsy of the
exam or epidemiological	lesion; cystercercosis antibodies; schistosomiasis (especially
context)	for spinal cord lesion)
Malignancy	
Lymphoma (Primary CNS or	SPEP/IFE, LDH, CSF flow cytometry and cytology*, body
Systemic with neurological	imaging (CT, FDG PET), histology
involvement)	
Meningeal carcinomatosis	MRI, CSF cytology, evidence of metastatic carcinoma on
	examination and body imaging.
CNS tumors (glioma, germ cell	MRI, biopsy
tumor, craniopharyngioma)	
Histiocytosis	Systemic involvement, Body imaging, Biopsy
Other Neuro-inflammatory	
Disorders	
Multiple sclerosis	MS diagnostic criteria e33 based on clinical course and MRI
	findings; CSF IgG index and oligoclonal bands can be helpful
	para-clinical markers.

Neuromyelitis optica	NMO diagnostic criteria <sup>e34</sup> , AQP4 IgG*; MRI findings (the
	pattern of enhancement in myelitis from NMO is typically
	intraparenchymal versus subpial involvement in the myelitis
	of neurosarcoidosis). <sup>e5</sup>
Tumefactive / Fulminant	Imaging features, biopsy
Demyelinating Process	
Acute Disseminated	Initial diagnosis based on clinical features and routine
Encephalomyelitis	testing. e35
Primary CNS Vasculitis e36	Clinical course, MRI findings, Angiography (including digital
	subtraction angiograph), Biopsy
CNS or PNS involvement from	Anti-neutrophil cytoplasmic and proteinase 3 antibodies
systemic vasculitis	(particularly for PNS manifestations), Cryoglobulins,
	Rheumatoid Factor, Complement, ANA, SSA, Hepatitis C
	antibody, hepatitis B serologies, renal markers (Creatinine,
	urinalysis). Evidence for systemic involvement, which may
	include involvement of skin, kidneys, lungs, sinuses, and
	other sites of injury. Granulomatosis with polyangiitis can
	manifest with pachymeningitis. e37
Lymphocytic hypophysitis	Isolated pituitary involvement; biopsy with demonstration of a
	mixed cellular inflammatory infiltrate and fibrosis.
	Granulomatous hypophysitis may be considered a
	manifestation of sarcoidosis versus an organ-specific
	granulomatous process depending on clinical context.
Chronic lymphocytic	Pontine perivascular enhancement on MRI responsive to
inflammation with pontine	corticosteroids; biopsy

perivascular enhancement	
responsive to steroids	
(CLIPPERS) e38	
Autoimmune astrocytopathy e39	Inflammation of the meninges, brain, and spinal cord with
	peri-vascular enhancement and longitudinally extensive
	spinal cord lesions on MRI. Glial fibrillary acidic protein
	(GFAP) IgG positive.
Myelin oligodendrocyte	MOG IgG antibody positive. MRI lesions tend to be bilateral,
glycoprotein (MOG) antibody-	large and "fluffy", and involve subcortical and deep structures
associated disease e40	as well as the brainstem.
Neurologic Involvement from a	
Systemic Disorder	
Systemic lupus erythematosus	SLE diagnostic criteria e41 ANA, double-stranded DNA and
	associated assays*
IgG4-related hypertrophic	Serum IgG subsets for IgG4 elevation may be suggestive but
pachymeningitis	is not specific. IgG4-related disorders may include
e42 43	pachymeningitis as part of systemic disease involvement.
	Tissue biopsy is definitive.
Sjogren's syndrome	(For evaluation of peripheral nervous system involvement)
	SSA and SSB serologies, sicca symptoms, lip biopsy,
	sialography or salivary flow. <sup>e44</sup> Caution is advised in
	correlating CNS findings with Sjogren's syndrome,
	particularly in the absence of histology. Note that sicca
	symptoms in isolation are not specific for Sjogren's
	syndrome and can also be seen in sarcoidosis.

Behcet's disease	Behcet's diagnostic criteria e45: Recurrent oral aphthous
	ulcers, plus any two of the following: positive Pathergy test,
	recurrent genital ulcers, eye lesions, characteristic skin
	lesions
Vogt-Koyanagi-Harada disease	Can cause recurrent meningitis in the context of severe
	uveitis, usually with cystoid macular edema as a prominent
	feature; not usually a chronic meningitis. Slit-lamp exam,
	fluorescein angiography, examination of the CSF
	(pleocytosis, melanin-laden macrophages), magnetic
	resonance imaging (MRI), and electrophysiologic testing e46
Common variable	Hypogammaglobulinemia. CVID may be associated with
immunodeficiency (CVID)	granulomatous disease that resembles sarcoidosis. e47 CNS
	and PNS manifestations can occur due to infection or
	inflammation. e48
CSF Pressure Dynamics	
Syndrome of Intracranial	Diffuse pachymeningeal enhancement, often with other signs
Hypotension (SIH) / CSF leak	of brain sagging; low CSF opening pressure; low pressure
	headache syndrome, search for CSF leak
Vascular	
Dural arterio-venous fistula	CT angiography or MRI angiography. Digital subtraction
(brain or spinal cord) or other	angiography for definitive evaluation.
vascular malformations such as	
AVM	
Stroke	Ischemic and hemorrhagic stroke (which may relate to
	vascular inflammation, of large or small arteries or veins).

	Also consider cardiac sources of emboli from arrhythmias or	
	congestive heart failure.	
Other Disorders		
Cancer-associated granulomas	Occasionally granulomas can be manifest in regional lymph	
	nodes or tissue proximate to a malignancy. A mass lesion	
	not responding to immunosuppressive treatment may need	
	to be biopsied, at times repeatedly	

<sup>\*:</sup> These tests should be considered in all patients being evaluated for the diagnosis of neurosarcoidosis unless there is a specific contraindication to obtaining the test (e.g. CNS mass effect precluding a LP).

	1			

Footnote 1. Two criteria were required to be fulfilled to apply the criteria: 1) histologic evidence of granulomatous inflammation of unknown cause ... in at least one organ that was not being assessed; 2) the clinical manifestation being assessed required that all alternative causes other than sarcoidosis ... had been reasonably excluded.

Footnote 2. At least two of six examinations need to be positive: bilateral hilar lymphadenopathy, abnormal uptake of 67 Ga scintigraphy, bronchoalveolar lavage fluid examination, elevated serum ACE, negative tuberculin reaction, and elevated serum or urinary calcium level.

Footnote 3. Assumes rigorous exclusion of other potential causes to the neurologic syndrome, particularly infection and malignancy.
